# Application of deep neural networks to retrieve cloud properties for Sentinel-4 (S4) and TROPOMI / Sentinel-5 Precursor (S5P)

Doctoral Candidates' Day 2022

Fabian Romahn

German Aerospace Center (DLR)

# Copernicus Satellites S5P and S4

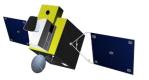

Sentinel-5 Precursor (S5P) and Sentinel-4 (S4) are passive earth observation satellites (with UV/VIS spectrometers) of the Copernicus programme:

### S5P:

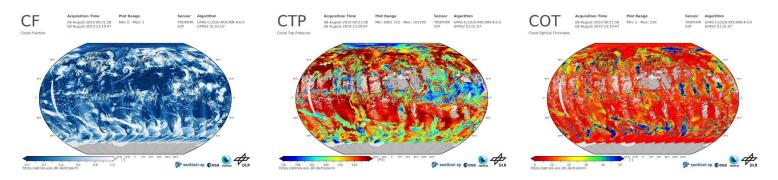

- Launched in october 2017
- Sun-synchronous orbit at ~ 824 km

- **S4**:
  - Launch date due 2023
- Geostationary

DLR is responsible for the operational CLOUD product for both satellites

Challenges:

- Large amouts of data
- Near real time requirements (NRT)
- $\rightarrow$  Application of machine learning techniques to improve performance compared to classical algorithms

# Application of neural networks

### **Problem:**

Find parameters x that minimize residual  $||F(x) - y||_2$  between a known vector y and the mapping of the parameters F(x)

- where F is a predefined function

for remote sensing:

x: State of atmosphere, y: Measured spectrum, F: Radiative transfer model (RTM)

### Two approaches:

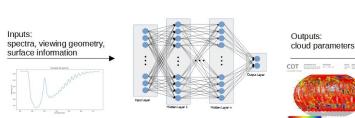

- NN as **forward model** of a spectral fitting algorithm: 1.
  - $F: X \to Y$  state of atmosphere  $\to$  spectrum
  - substitutes and approximates the RTM ٠
  - gradients (w.r.t to retrieval pamareters) • usually need to be provided for solver
  - called in each iteration ٠
- 2. NN for **direct inversion**:
  - $F^{-1}$ :  $Y \to X$ , spectrum  $\to$  state of atmosphere
  - $F^{-1}$  is generally unknown, • can only be inferred through samples
  - No gradients needed after learnnig
  - called only once

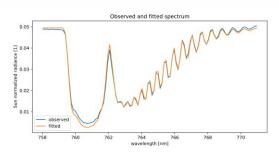

Inversion with RTM as Forward Model

Inversion with NN as Forward Model

Forward Model

# NN as forward model

How to get from RTM to NN?

→ NN Lifecycle chain: General procedure to replace RTM of an inversion algorithm by a NN

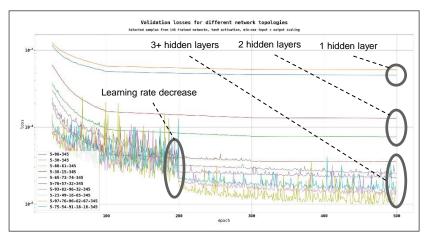

Finding optimal NN configuration is challenging, aspects:

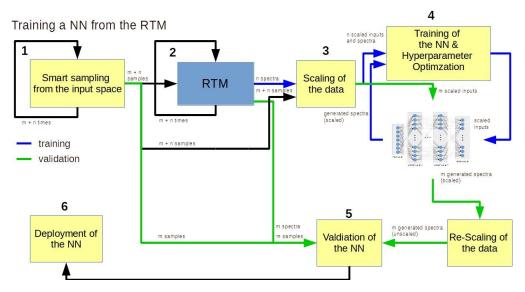

- NN topology

. . .

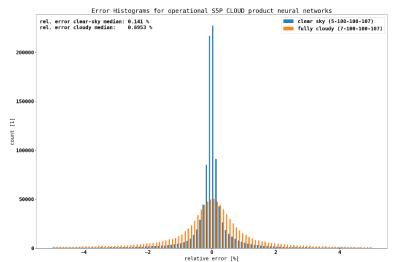

- activation functions
- dataset sampling
- learning algorithm

## NN performances for different topologies

### Operational S5P NN performance

# Spectral fitting challenges

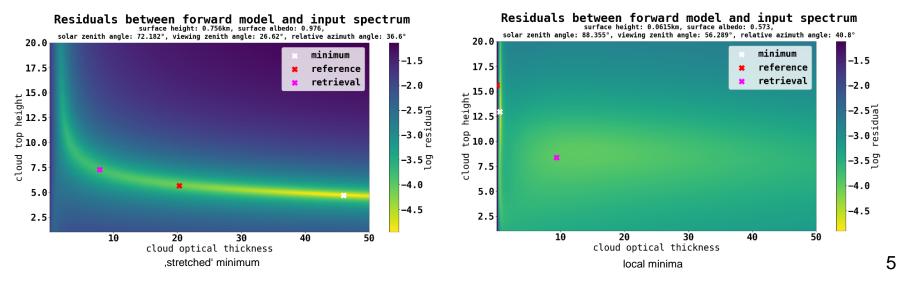

With a NN as forward model, a spectral fitting algorithm can be used for the retrieval of the atmospheric parameters

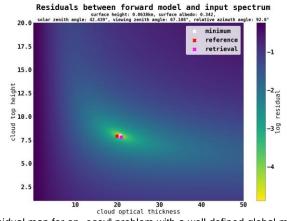

However, this is still challenging:

- spectral fitting problem is generally ill-posed
  → local minima
- real data contains noise in measurements

→ ROCINN algorithm (part of the operational S5P CLOUD product) uses **Tikhonov Inversion**, which adds a regularization term to the optimization problem

For difficult cases, good a-priori values for the retrieval parameters are still important

Residual map for an "easy" problem with a well defined global minimum

# NN for direct Inversion

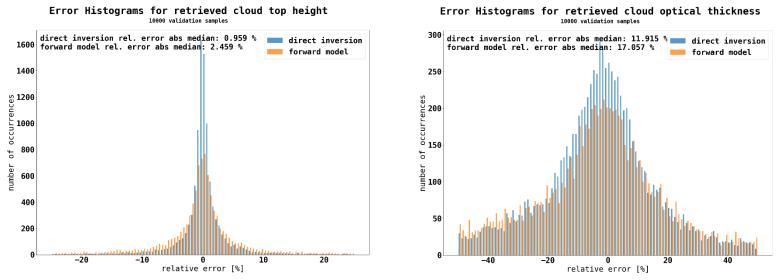

NN for direct inversion can avoid some of the issues of the spectral fitting:

- no fine adjustment of the retrieval algorithm (e.g. regularization parameter, tolerances for convergence, etc.), all settings via the hyperparameters and training of the network
- no a-priori necessary
- not as affected by local minima
- not as affected by local minima

Input: spectra, viewing geometry, surface parameters, Output: cloud parameters evaluation for comparison with forward model NN in spectra fitting for validation dataset:

> topologies: NN as forward model: NN for direct inversion: 112-80-80-80-2

7-66-77-26-89-78-94-99-107

→ Better results for direct inversion NN: CTH: 0.96% vs 2.46%, COT: 11.92% vs. 17.06% (med. abs. rel. error)

# **Bayesian Neural Networks**

Drawback: No indication for the quality of the results for the direct inversion NN (*"blackbox"*) In contrast to the spectral fitting with e.g. iterations, convergence, residual, etc.

### →Bayesian neural networks (BNN):

- · learns uncertainties in model parameters
- · output is a probability distribution
- · more complex and are harder to train

### Evaluation:

- 1. Overall, BNN performs slightly worse than the conventional NN (taking the means as output)
  - learning is harder (much slower), current results are likely not optimal
  - for many deep topologies (> 3 hidden layers) learning is not successful
- 2. Standard deviation of ouptuts allows definition of a confidence interval
  - reference values are mostly inside
    → reliable quantification of errors

# ПΠ

# **Conclusions and Outlook**

### 1. NN as forward models:

- can improve speed of existing retrieval algorithms by orders of magnitude through substitution of existing radiative transfer model (RTM)
- many properties from classical retrieval algorithms are inherited:
  - retrieval diagnostics
  - difficulties with ill posed problems, local minima

### 2. NN for direct inversion:

- easy to apply, good initial performance, no a-priori needed
- conventional NNs are "black boxes", no error quantification
- BNNs as a possibility to overcome this:
  - provide error quantifications
  - more complex and harder to train

→NNs for direct inversion, especially when using BNNs with error quantification, have great potential for retrieving cloud properties for S4 / S5P as an alternative to the current approach that uses NNs as forward models

- Further investigations in hyperparameter selction and learning have to be made
- Invertible neural networks (INN), that learn forwards and backwards and can also provide distributions are another interesting approach that should be followed
